ABSTRACT

This paper demonstrates the applicability and benefits of optimal design of experiments (ODOE) for architecting systems-of-systems (SoSs). All experiments depend on appropriate models for their design and analysis. In keeping with the sparsity-of-effects principle, a general linear model with main-effects-plus-two-factor-interactions (MEPTFI) is assumed to realistically characterize the relationship between the SoS elements and the response of interest. The designed experiment requires additional simulations to account for the two-factor interaction effects, and the main effects cannot be interpreted as defining the optimal solution. The optimal performance architecture is determined by optimizing the fitted MEPTFI model. The proposed method is applied to the problem of architecting a SoS to protect against small boat attacks. A statistical analysis confirms that the MEPTFI model has excellent predictive capability. It also proves the fallacy of the applicability of the standard Taguchi method for architecting SoSs by demonstrating that it gives misleading results because of the omission of active interactions. The ODOE method can be implemented using commercially available general-purpose statistics software. Given its mathematical formulation, it can be generalized to solve systems engineering and architecting problems that require complex models beyond the MEPTFI model. © 2014 Wiley Periodicals, Inc. *Syst Eng* 17: 426–441, 2014

1. INTRODUCTION

Design of experiments (DOE) is a structured approach to designing and analyzing experiments in which purposeful changes are made to multiple input variables (or factors) to efficiently investigate the effects on an output variable (or

response) [Kleijnen et al., 2005]. It has a long and illustrious history since Fisher [1926] founded the underlying principles of design and statistical analysis of designed experiments in the 1920s and early 1930s. Montgomery [2012: 22] notes that “There is not a single area of science and engineering that has not successfully employed statistically designed experiments.” The early applications principally used 2-level full factorial and fractional factorial designs (FFDs). Full factorial designs consider all combinations of factors and an experiment with k 2-level factors require 2^k runs. FFDs drop some of the factorial combinations to reduce the number of runs,
