

3.9 DNA replication and the genetic code

- When the cell divides, two strands of DNA separate and each strand is a template for the creation of new double helix.
- The complementary base pairing ensure that the new helix is identical to the original.

Semi-conservative replication:

- Firstly, DNA Helicase unwinds and separates the two strands of DNA- the H bonds between the bases are broken.
- Free nucleotides then pair up with complementary bases, bonding with H bonds.
- Lastly, the new nucleotides join to their adjacent nucleotides with Phosphodiester bonds, catalysed by DNA Polymerase II
- The new DNA now has half of the old, and half of the new bases.

Role of enzymes in replication:

- DNA replication is controlled by enzymes.
- **DNA helicase** unwinds and separates the two strands of DNA.
- It travels along the DNA backbone, catalysing the breaking of H bonds.
- **DNA polymerase** catalyses the formation of phosphodiester bonds between the nucleotides.
- An error in matching of base pairs leads to changes in coding sequence resulting in **mutation**.
