Sustainable exploration of the solar system requires a large amount of material and propellant to be transported out of Earth
s gravity well and onwards to their destination Despite recent advances in lowering launch costs transferring material from
Earth to space is still very costly It still amounts to several thousand to tens of thousands of Euros per kilogram to low earth
orbit and transportation to the Moon and Mars even a multiple of that There is an abundance of resources in our solar system
that can be utilized to reduce the material required to be launched from Earth significantly Among these resources are water
ice hydrates metals regolith rare earth elements chemical compounds volatiles and rare isotopes Utilizing these space
resources would enable e g consumable and propellant production in space manufacturing or the construction of large
structures which would otherwise be very expensive or not possible at all with material launched from Earth Lunar regolith
for example contains iron and titanium that could be used to produce spacecraft components or structural elements for a
lunar base while oxygen released from oxide minerals could be used for respiration or as a propellant In addition water ice
could be extracted from regolith and used for consumption or agricultural applications Although there have been numerous
missions to the Moon there are still a lot of unknowns concerning its surface making it difficult to know where to look for
resources and how to extract them **Medical Record** George Frederick Shrad,y,Thomas Lathrop Stedman,1902
