

1. Introduction to Wind Forces and Wind Effects on Buildings and Structures

1.1. Nature and Causes of Wind

Wind is simply a movement of the earth's atmosphere from areas of high pressure to areas of low pressure to equalize the pressures. Air pressure is a measure of the weight of the air on the surface of the earth. The difference in pressures is related to the rising and sinking of air. Rising air causes low pressure and sinking of air causes high pressure. Air pressures are generally connected to the temperature differences of the various parts of the globe and to the rotation of the earth. Warm air near the equator rises, creating an area of low pressure, and moves toward the colder regions near the poles, leading to high pressure in those regions. A general wind circulation takes place with air from the polar high-pressure areas moving to replace the rising air in the low-pressure warmer areas.

1.2. General Overview of Building Design for Wind

Wind effects on buildings and structures are complex. However, and in order to develop design methods for buildings and structures, it is often necessary to simplify these wind effects. For instance, the wind velocity and direction are rarely constant in a wind event. Wind can change in velocity and direction fairly quickly in some cases. Building codes and standards generally provide different design methods depending on the type of building or structure in question. In some cases, it is acceptable to use some simplified design procedures. In these procedures wind direction and velocity may be considered constant. The wind direction is often considered horizontal, leading to lateral forces on buildings. In some other cases, buildings and structures must be designed using wind tunnel procedures by creating reduced-scale models of the structure, and testing these models in a wind tunnel facility. Wind conditions that are closer to reality are recreated in a wind tunnel laboratory, and reduced-scale models are subjected to them and studied for wind effects.

The general procedure in designing buildings for wind forces is to consider the wind effect in the form of pressure applied to various building surfaces. These wind pressures are then converted into wind forces applied to structural members that must be designed to resist these forces.

The term pressure in physics simply means the force that is applied per unit area of surface. When discussing wind pressure on building surfaces, the unit often used to express the pressure is psf, pounds per square foot (or N/m^2 using metric units). Pressure is considered as applied in a direction that is perpendicular to the surface in question. In our discussion here, pressure is a consequence of air flow.

At this time, buildings in the United States are designed according to the *International Building Code (IBC)* and the *International Residential Code (IRC)*. The current editions are the 2015 editions for both codes.^{1,2} The structural chapters of these codes are generally based on a standard published by the American Society of Civil Engineers (ASCE): *Minimum Design Loads for Buildings and Other Structures*, often referred to as the ASCE 7 standard. The current version of this standard is the 2016 edition.³ The title of the current version was slightly changed from the previous ASCE 7-10 to *Minimum Design Loads and Associated Criteria for Buildings and Other Structures*. The building design procedures according to the ASCE 7 standard will be covered in this book. In this first chapter, some of the most basic concepts of wind design are summarized. It is important for the reader to understand some of the elementary terms and principles associated with wind design, and to have an idea about the historic basis and context of these principles as explained in this chapter.
