ABSTRACT

Available experimental data on Mylar stopping powers (SP s) for heavy ions (HIs) at energies $0.04 \leq E/A \leq 15$ MeV/nucleon have been compared to different semi-empirical model calculations with the aim of their possible usage for the estimates of ranges for very heavy ions at $E/A < 0.5$ MeV/nucleon, which are of practical interest. Significant deviations from the calculated SP values were found for fission fragments and lighter HIs at $E/A < 1$ MeV/nucleon. A new model parameterization for Mylar SP has been proposed. Range estimates obtained with any SP model calculation show a critical dependence of their mean values on the approximated electronic stopping powers and the nuclear (collisional) SP component. The last plays a crucial role at the end of the range and could only be obtained by calculations. Practical applicability of the results of investigation for very heavy evaporation residues (products of complete fusion reactions induced by HIs) implies the use of a thick catcher foil corresponding to the largest ranges derived in the estimates or the range measurements for these products.

1. Introduction

In practice, we often need ranges of heavy evaporation residues (ERs) that produce complete fusion reactions induced by heavy ions (HIs) to assess the effectiveness of commissioning setups designed for the separation and detection of these extremely heavy ions. A gas-filled solenoid GASSOL [1] is an example of such a setup, which is scheduled to go into operation in the near future. The Mylar foil of a defined thickness is a good choice as a catcher for ERs collection in the focal plane of the solenoid. Typical energies for Rn to Th ERs produced in test reactions with medium-heavy ions (from Ar to Ni) are below 0.5 MeV/nucleon. SRIM calculations [2] show very narrow range distributions for mono-energetic Rn to Th ions of respective energies in Mylar. This implies the use of a foil of a definite thickness accompanied by some pre-stopper for unambiguous identification of the collected reaction products, such as α -radioactive ERs in particular. Obviously, the real range straggling (width of the distribution) is larger due to the evaporation of light particles from the compound nucleus formed in the chosen reaction and ERs stopping inside a target used in an experiment [3].

Stopping of Heavy Ions Peter Sigmund, 2004-07-09 This book offers a concise presentation of theoretical concepts characterizing and quantifying the slowing down of swift heavy ions in matter Although the penetration of charged particles through matter has been studied for almost a hundred years the quantitative theory for swift penetrating ions heavier than helium has been developed mainly during the past decade and is still progressing rapidly The book addresses scientists and engineers working at accelerators with an interest in materials analysis and modification medical diagnostics and therapy mass spectrometry and radiation damage as well as atomic and nuclear physicists Although not a textbook this monograph represents a unique source of state of the art information that is useful to a university teacher in any course involving the interaction of charged particles with matter
