Abstract This paper documents a model that was pivotal in deciding which of two architectures should be selected for a frame relay data communications network The choices are either to continue using the current architecture or to make a large incremental investment in new equipment which reduces the number of high speed inter office trunks required to interconnect the switches The analysis requires optimizing the mix of two types of customer port cards to determine the maximum customer port capacity of a switch Simple approximations are used to estimate the number of inter office trunks and trunk cards required Based in large part on the costs computed by this model an executive level decision was made to move to the new architecture
