Forensic Science Progress ,2012-12-06 Among the samples collected from the crime scene tissue samples such as bone tooth hair nail skin muscle and others are very important trace evidence which provide us with available information for personal identification In order to obtain such information these tissue samples should be thoroughly examined using conventional methods including morphology and histo pathology as well as blood grouping Through the methods described above blood grouping will give us reliable information for personal identification to a high degree of certainty In order to succeed in determining blood groups from tissue samples the techniques used should be carefully selected because the content and the distribution of blood group substances are different for various tissue samples Moreover blood group antigen activities are susceptible to postmortem changes leading to the lowering of their activities From this point of view it is essential to adopt a specific and highly sensitive technique for grouping of tissue samples for routine use Depending on tissue conditions adequate pre treatment of the samples will be required for concentrating blood group substances For routine blood grouping of tissue samples the absorption inhibition the hemagglutination inhibition and the absorption elution technique prevail and are most favoured in forensic science In cases of single epithelial cells and extremely small tissue fragments the mixed agglutination technique can be recommended Adding to these routine methods immunohistochemical techniques such as those using fluorescein labelled antibodies enzyme labelled antibodies and ferritin labelled antibodies have been recently applied to the blood grouping of tissue samples
