*Evolution of nuclear physics into the particle domain*

H.V. Klapdor, Heidelberg

(Max-Planck-Institut für Kernphysik)

Nuclear physics is presently experiencing a new impetus, addressing itself towards more fundamental physics questions and becoming more and more important as a test of physics beyond the standard model of grand unification. The close connections between the laws of microphysics, astrophysics and cosmology — one of the most significant discoveries of our century — open further exciting perspectives.

Among the most topical fields of activity (see K. Gabathuler, *Europhys. News*, Jan. 1987) are the search for a finite neutrino mass by  $\beta$ -end-point spectroscopy, neutrinoless double beta decay and neutrino oscillations, proton decay, the study of rare and forbidden muon and pion decays and the search for an electric dipole moment of the neutron — all experiments which are complementary to the direct search for new particles and symmetries in high energy experiments — and their relations to grand unification, superstring theories and the evolution of the early Universe. Other topics which not so long ago would have been regarded exclusively as particle physics are the status of electroweak gauge theories, in particular the mixing of quarks by the weak interaction and the origin of the observed CP violation, quarks in nucleons and nuclei, etc. Even traditional fields of nuclear physics carry the same message: the discussions on the positron lines observed at GSI in collisions of nuclei with high  $Z$ ; the observation of extremely high spins in super-deformed nuclei; new results on the parity violation in quasi-elastic electron scattering; properties of exotic nuclei and of nuclear matter. But this is now close to astrophysics — the collapse of heavy stars, baryon and lepton number conservation and weak interactions in cosmology.

Weak interactions are of basic importance for the development and structure of the Universe because:

- without weak interactions there would be no heavy elements;
- neutrinos could determine by their

*This review of developments in nuclear physics is largely based on discussions at the EPS and RARLP sponsored International Symposium on Weak and Electromagnetic Interactions in Nuclei, WEJIN 1986, held in Heidelberg, 1-5 July 1986, in conjunction with the 500th anniversary of the University of Heidelberg. About 300 participants worldwide attended the Conference, which was held under the patronage of the Rector of the University, Gisbert zu Putlitz and chaired by the author. Several countries expressed their interest in hosting a similar WEJIN conference in 1989. The Proceedings have been published recently by Springer-Verlag.*

mass, whether the Universe is open or closed;

- neutrinos are the best candidates for the non-baryonic dark matter in the Universe, which could represent more than 90% of the mass of the cosmos;
- problems of the weak interaction, such as the mass of the neutrino, are — together with the half-life of the proton — key points for the structure of grand unification theories (GUTs) or supersymmetry theories (SUSYs) which must include the development of the early Universe.

## Neutrinos

Today, 30 years after the direct observation of the neutrino in the famous Goldhaber experiment, it is still unknown whether the neutrino has a mass or not, and all over the world there are different projects trying to resolve the question.

The European Gallex group (Gallium Experiment) headed by the MPI in Heidelberg plans to detect solar neutrinos in the Gran Sasso tunnel near Rome; R. Mössbauer and his group are looking for neutrino oscillations using the core of

a nuclear power reactor as a neutrino source. Both these experiments are looking for differences in the masses of different neutrino types. Solar neutrino experiments with other detectors are expected to yield answers to the recent question of neutrino-matter oscillations.

Two other types of experiment attack the mass question directly. W. Kündig in Zürich studies the beta decay of tritium and has reported an upper limit of 18 eV. A different method is to measure the half-life for neutrinoless double beta decay and here the most active groups are in Osaka, Columbia, Milan, Zaragoza and Santa Barbara.

To deduce the neutrino mass from observations of the decay, additional nuclear structure information is needed, but using the most recent calculations of the nuclear matrix elements done in Heidelberg, the mass of the electron neutrino turns out to be less than 1 eV. This limit corresponds, however, to an effective mass only. If more than one Majorana neutrino couples to the electron, as the interference between the different mass states of the neutrinos in the neutrino exchange amplitude could be destructive, the true mass of the electron neutrino could be substantially larger. If one assumes a second neutrino with a mass not smaller than 100 MeV, a conservative limit for the electron neutrino mass is then 13 eV. Of particular interest are the Osaka group's studies of the  $0^+ \rightarrow 2^+$  transitions which in contrast to the  $0^+ \rightarrow 0^+$  ground state transitions, can be driven by right-handed currents only, not by a mass term, and further efforts to look for a neutrinoless decay branch with emission of a light boson, the majoron.

To reduce further the limit on the half-life for neutrinoless  $\beta\beta$  decay by more than an order of magnitude, a collaboration from Heidelberg, Leningrad, Moscow, and Bordeaux is planning to use enriched  $^{76}\text{Ge}$  inside a well-shielded cavity. The Soviet Union will provide the enriched material.

An important constraint for deducing
