**METAL-MATRIX COMPOSITES (MMC's)** are engineered combinations of two or more materials in which reinforcing phases are dispersed in a metal or an alloy. Structurally, cast MMC's consist of continuous or discontinuous fibers (designated by the subscript *f*), whiskers (*w*), or particles (*p*) in a metal or an alloy that solidifies in the restricted spaces between the reinforcing phase (or phases) to form the bulk of the matrix. There are several cast materials, such as aluminum-silicon alloys and cast irons, that exhibit two-phase microstructures in which the volume and shape of the phases are governed by phase equilibria and that have a long history of foundry production. Modern cast MMC's differ from these traditional materials in that any selected volume, shape, and size of reinforcement can be introduced into the matrix, even beyond the permissible limits presented by the phase diagrams.

By carefully controlling fiber size, shape, surface properties, volume fraction, and distribution of the reinforcement and by controlling the solidification conditions, MMC's can be synthesized having a tailored set of useful engineering properties. For example, as shown in Table 1, combinations of very high specific strength and specific modulus, beyond those of conventional monolithic alloys, are achievable. Table 2 summarizes the applications of several commonly used MMC's and the properties that make them suitable for

their applications. Microstructural design and synthesis procedures have been developed to achieve unique combinations of properties, including improved elevated-temperature and fatigue strengths, increased damping ability, tailored electrical and thermal conductivities,

reduced wear rates, and targeted coefficients of thermal expansion. These tailored properties provide opportunities for a variety of new applications for MMC's that were not possible using conventional materials. For more information about MMC types and their applications, see the

Nucleation Phenomenon During Solidification of Metal Matrix Composites ,1994

A detailed analysis of possible interfaces in cast aluminum silicon base reinforced particle composites containing SiC Al<sub>2</sub>O<sub>3</sub> and C indicates that several different kinds of interfaces can form The reinforcements may be totally surrounded by primary

phase or primary silicon or by the eutectic between Al and Si In addition in some cases some of the original coatings or their reaction products in the case of coated particles like nickel or nickel aluminum intermetallics in nickel coated reinforcements Cu or Cu aluminum intermetallics in Cu coated reinforcements may also form the interface The reaction between dispersoids and the alloy itself can form a complex interface These different interfaces have also been experimentally observed in the microstructures of cast particulate composites with the exception of primary  $\alpha$  aluminum surrounding the reinforcement The absence of  $\alpha$  aluminum on the reinforcements is attributed to possible lack of nucleation persistent lateral growth and a thermal lag between the reinforcement and the matrix Estimates of works of adhesion for the different interfaces observed in cast composites have been made using the London Van der Waal equation correlated to the properties of the composites and used to identify the possibilities of further improving these properties

result is obtained by fabrication of LM6 TiCp MMC using copper mould permanent die the maximum mean value of hardness 76 82 Rockwell number is reached by addition of 25% TiCp volume content solidification time fraction equals to 1 at 5 seconds fastest and volumetric latent heat generated 100 77 kJ m<sup>3</sup> From the results it is concluded that casting of LM6 TiCp MMC is successfully achieved using vortex mixing technique and that addition of particulates influence solidification characteristics which in turn affect the properties of the MMC
