## **Stability And Optimization Of Flexible Space Structures:**

Stability and Optimization of Flexible Space Structures S.J. Britvec, 2012-12-06 The aim of this book is to present up to date methodologies in the analysis and optimization of the elastic stability of lightweight statically determinate and indeterminate space structures made of flexible members which are highly stiff when loaded centrally at the nodes These are flat and curved space pin connected open or enveloped lattices and reticulated shells which due to their high loadbearing capacity to weight ratios are gaining in importance in aerospace and other fields They are utilized for example in space stations as support structures for large radio telescopes and for other equipment on earth and in outer space as roof structures for the coverage and enclosure of large areas on earth and as underwater shell type structures enveloped by a cover shell capable of withstanding high hydrostatic pressures Space structures of this type are generally subjected to considerable internal axial loads in the flexible members and they fail through the loss of global statical stability usually precipitated by the intrinsic small imperfections at finite near critical elastic deformations and not primarily by the the break down of the material of which they are made as is the case in conventional systems Thus the criterion in the design of such structures calls for eliminating or isolating the onset of the elastic dynamic collapse thereby increasing their safe stability limit Standard finite element methods as they are employed by most users today are totally inadequate for such analyses since they do not account for the choice of the branching paths in the loading process of the structure nor for the existence of the relevant collapse modes These aspects are novel and they are presented here for the first time in comprehensive book form

*High Performance, Robust Control of Flexible Space Structures* Mark S. Whorton, 1997 Many spacecraft systems have ambitious objectives that place stringent requirements in terms of pointing and vibration control

systems Because of the difficulty of obtaining accurate models for flexible space structures limitations must be placed on performance in order to ensure stability In some cases to achieve sufficiently high performance to accomplish mission objectives will require the ability to refine the control design model based on closed loop test data and tune the controller based on the refined model The objective of this thesis is to develop a procedure for control system design which maximizes achievable performance with robust stability guarantees Two facts of this dissertation are control design and system identification A control design and system identification A control design procedure is developed based on mixed H<sub>2</sub> H<sub>∞</sub> Infinite symbol subscript optimization which is used to design a set of controllers which explicitly trade between nominal performance and robust stability A homotopy algorithm is presented which generates a trajectory of gains along the boundary which trades between robustness and performance This set of controllers may be implemented to determine the maximum achievable performance for a given model error bound Examples are given which show that a better balance between robustness and performance is obtained using the mixed H<sub>2</sub> H<sub>∞</sub> Infinite symbol subscript design method than either H<sub>2</sub> or synthesis control design A second contribution of this dissertation is a new procedure for closed loop system identification Using closed loop response data the parameters of a control design model in a canonical realization are refined Examples are provided to demonstrate the convergence of the parameter estimation and improved performance realized by using the refined model for controller redesign These developments result in an effective mechanism for achieving high performance control of flexible space structures

*Robustness Improvement of Actively Controlled Structures Through Integrated Structural/control Design* S. S. Rao, T. S. Pan, 1991 The problem of structural and control design of flexible structures is considered Three major topics are investigated The first topic deals with the dual passive active control design for flexible structures The interacting sub structure decentralized control approach is developed for large flexible structures to eliminate the spillover problem and reduce the model size for controller margin and robustness of controlled flexible structures The second topic considers the robustness improvement for controlled flexible structures through structure modifications The stability and engineering performance robustness indices are defined The integrated structural control design problem is considered as a multiobjective optimization problem in which three objectives structural weight stability robustness index and performance robustness index are considered for minimization The third topic involves the study of the actuator sensor location selection problem The sequential best adding penalty function method and the genetic algorithm are considered
