and Extensional Aspects of Lisp-type Computation Carolyn L. Talcott, Stanford University. Computer Science Department, 1985 Rum is a theory of applicative side effect free computations over an algebraic data structure It goes beyond a theory of functions computed by programs treating both intensional and extensional aspects of computation Powerful programming tools such as streams object oriented programming escape mechanisms and co routines can be represented Intensional properties include the number of multiplications executed the number of context switches and the maximum stack depth required in a computation Extensional properties include notions of equality for streams and co routines and characterization of functionals implementing strategies for searching tree structured spaces Precise definitions of informal concepts such as stream and co routine are given and their mathematical theory is developed Operations on programs treated include program transformations which introduce functional and control abstractions a compiling morphism that provides a representation of control abstractions as functional abstractions and operations that transform intensional properties to extensional properties The goal is not only to account for programming practice in Lisp but also to improve practice by providing mathematical tools for developing programs and building programming systems Rum views computation as a process of generating computation structures trees for context independent computations and sequences for context dependent computations The recursion theorem gives a fixed point function that computes computationally minimal fixed points The context insensitivity theorem says that context dependent computations are uniformly parameterized by the calling context and that computations in which context dependence is localized can be treated like context independent computations
