**Space-Time Coding** Branka Vucetic, Jinhong Yuan, 2003-06-02 The capacity of wireless data communications is lagging behind demands due to unsatisfactory performance of the existing wireless networks such as low data rates low spectral efficiency and low quality of service Space time coding is an effective transmit diversity technique to combat fading in wireless communications Space time codes are a highly bandwidth efficient approach to signalling within wireless communication that takes advantage of the spatial dimension by transmitting a number of data streams using multiple co located antennas There are various approaches to the coding structures including space time trellis coded modulation space time turbo codes and also layered architectures The central issue in all these various coding structures is the exploitation of multipath effects in order to achieve very high spectral efficiencies The spectral efficiencies of traditional wireless systems range between 1.5 bps sec Hz but by using space time techniques spectral efficiencies of 20-40 bps sec Hz have been possible Hence space time coding enables an increase in capacity by an order of magnitude This is the main reason why space time codes have been included in the standards for the third generation wireless communication systems and ultimately why Space time Coding will be in great demand by individuals within industry and academia The comprehensive understanding of space time coding is essential in the implementation of 3G and as the only title currently

available Space Time Coding will be the standard text for Researchers telecommunication engineers and network planners academics and undergraduate postgraduate students telecommunications managers and consultants Turbo Coding, Turbo Equalisation and Space-Time Coding Lajos Hanzo, T. **Optical Communication Theory and Techniques** Enrico Forestieri, 2004-10-21 Since the advent of optical communications a great technological effort has been devoted to the exploitation of the huge bandwidth of optical fibers Starting from a few Mb/s single channel systems a fast and constant technological development has led to the actual 10 Gb/s per channel dense wavelength division multiplexing DWDM systems with dozens of channels on a single fiber Transmitters and receivers are now ready for 40 Gb/s whereas hundreds of channels can be simultaneously amplified by optical amplifiers Nevertheless despite such a pace in technological progress optical communications are still in a primitive stage if compared for instance to radio communications the widely spread on-off keying OOK modulation format is equivalent to the rough amplitude modulation AM format whereas the DWDM technique is nothing more than the optical version of the frequency division multiplexing FDM technique Moreover adaptive equalization channel coding or maximum likelihood detection are still considered something exotic in the optical world This is mainly due to the favourable characteristics of the fiber optic channel large bandwidth low attenuation channel stability which so far allowed us to use very simple transmission and detection

and correct errors in transmitted data. It is also a valuable technique to reduce the power requirement thus have an important role in these systems. This reduction in power requirement is achieved at the expense of an increase in bandwidth requirement. The objective is usually to find error control techniques that give good tradeoff between power and bandwidth requirements. In this thesis we present results for FEC technique using Turbo Block Codes and Turbo Product Codes. It is shown that these codes not only in theory but also in hardware implementation are capable of providing significant performance gains over other error correction schemes. This thesis investigates Trellis based iterative decoding techniques applied to concatenated coding schemes Turbo Block Codes. We use RM  $n, k$  to construct 2-D and multi dimensional Turbo Block Codes. Our objective is to get high code rates and long block sizes for more bandwidth efficiency and improving the performance of the optimised maximum a posteriori decoding algorithm.

**Iterative Decoding for Trellis Based Codes in Wireless Communications** Huijun Chen, 2008 Abstract In this dissertation we focus on three issues of the trellis based iterative decoding. First the complexity issue of Turbo code is considered. We propose a constrained iterative decoder to reduce the decoding complexity. An additional interleaver is introduced at the encoder. At the decoder we first use Cyclic Redundance Code (CRC) to detect which bits are already correctly decoded during early iterations. With knowledge of the positions of these correct bits the constrained decoding algorithm is designed to reduce the number of the state transitions in the component code trellis and help the decoding of other bits in later iterations. In this way the constrained iterative decoder achieves significant complexity reduction and still satisfying performance. Second the iterative decoding algorithm is redesigned for Turbo code implemented Distributed Source Coding (DSC). When used in DSC the Turbo decoder encounters a combined Binary Symmetric Channel (BSC) and Additive White Gaussian Noise (AWGN) distortion. The existing iterative decoding algorithm based on AWGN distortion assumption causes performance degradation. By redefining the channel reliability values the modified iterative decoding algorithm matches the BSC AWGN scenario well and improves the performance. Third we propose a reliable source transmission coding and decoding scheme. A serially concatenated source and space time modulated coding structure is used. Variable Length Code (VLC) with error resilient capability is adopted at the application layer. Space Time Trellis Code (STTC) is used to provide high bandwidth efficiency at the physical layer. An iterative joint source space time decoder is designed including the symbol level space time Maximum A Posteriori (MAP) decoder, the bit level VLC MAP decoder and the Viterbi VLC decoder. Critical issues such as STTC MAP algorithm with nonseparable systematic information, VLC MAP algorithm in absence of channel output, VLC Viterbi algorithm based on the bit level trellis and extrinsic information conversion and exchange between bit domain and symbol domain are addressed. The decoding performance of different frame sizes and different component VLCs and STTCs, the rate allocation between the source code and the space time code and the performance in presence of channel estimation errors are discussed in this dissertation.
