[Statistical and Adaptive Signal Processing for UXO Discrimination for Next-Generation Sensor Data](#), 2009 To address the limitations associated with current sensors SERDP and

ESTCP have been supporting efforts to develop a new generation of UXO sensors that produce data streams of multi axis vector or gradiometric measurements for which optimal processing has not yet been carefully considered or developed Here we outline a research program where our goal was to address this processing gap employing a synergistic use of advanced phenomenological modeling and signal processing algorithms The focus of the research was i exploitation and refinement of Duke s existing phenomenological models to accurately predict the underlying target signatures for the new sensor modalities with the goal of pinpointing physical parameters that can be utilized within the signal processing architecture ii development of physics based statistical signal processing approaches applicable to the problem in which vector data is available from such sensors iii development of the theory of optimal experiments to guide the optimal deployment of sensor modalities and iv development of active learning and kernel based algorithms that yield target classification based upon all available data not based on individual feature vectors from isolated targets as well as allowing data collected across multiple sites to be integrated within the classifier

**Adaptive Filtering** Paulo S. R. Diniz, 2008-05-22 The field of Digital Signal Processing has developed so fast in the last three decades that it can be found in the graduate and undergraduate programs of most universities This development is related to the increasingly available technologies for implementing digital signal processing algorithms The tremendous growth of development in the digital signal processing area has turned some of its specialized areas into fields themselves If accurate information of the signals to be processed is available the designer can easily choose the most appropriate algorithm to process the signal When dealing with signals whose statistical properties are unknown fixed algorithms do not process these signals efficiently The solution is to use an adaptive filter that automatically changes its characteristics by optimizing the internal parameters The adaptive filtering algorithms are essential in many statistical signal processing applications Although the field of adaptive signal processing has been subject of research for over four decades it was in the eighties that a major growth occurred in research and applications Two main reasons can be credited to this growth the availability of implementation tools and the appearance of early textbooks exposing the subject in an organized manner Still today it is possible to observe many research developments in the area of adaptive filtering particularly addressing specific applications

Communications receivers are commonly optimized with respect to a stationary interference source When the interference originates in a composite source the optimal receiver may be represented as a collection of generically similar subreceivers each one of which is optimized with respect to one of the interference subsources Selection of the correct subreceiver is conditioned on identifying the subsources that is interfering at a given time This selection process is controlled by a statistical demultiplexer In the absence of real communications when the statistical demultiplexer operates on uncorrelated noise its function is to estimate the present state of a spectrally white non Gaussian nonstationary random process To evaluate the performance of the statistical demultiplexer it is necessary to assert that the state of the observed process is itself a stationary unobservable process Consideration is given to the case in which the unobservable is Markov When the receiver is an isolated system that draws power from a limited reservoir of energy and messages arrive only sporadically the statistical demultiplexer in its simplest form detects the mere presence of the message and control a switch in the power line to the main receiver subsystem The alertness strategy embodied in this scheme can greatly extend the life time of the system under conditions that are considered in some detail

Although adaptive filtering and adaptive array processing began with research and development efforts in the late 1950 s and early 1960 s it was not until the publication of the pioneering books by Honig and Messerschmitt in 1984 and Widrow and Stearns in 1985 that the field of adaptive signal processing began to emerge as a distinct discipline in its own right Since 1984 many new books have been published on adaptive signal processing which serve to define what we will refer to throughout this book as conventional adaptive signal processing These books deal primarily with basic architectures and algorithms for adaptive filtering and adaptive array processing with many of them emphasizing practical applications Most of the existing textbooks on adaptive signal processing focus on finite impulse response FIR filter structures that are trained with strategies based on steepest descent optimization or more precisely the least mean square LMS approximation to steepest descent While literally hundreds of archival research papers have been published that deal with more advanced adaptive filtering concepts none of the current books attempt to treat these advanced concepts in a unified framework The goal of this new book is to present a number of important but not so well known topics that currently exist scattered in the research literature The book also

documents some new results that have been conceived and developed through research conducted at the University of Illinois during the past five years
